## OBJECTIVE

The Residency Research Network of Texas (RRNeT) provides care for a unique patient population, with large proportions of low income, uninsured, and underrepresented minority people. RRNeT consists of 10 training sites where the focus of the visit may vary somewhat from standard private practice. These differences can bias our research findings on a variety of content areas, as they limit generalizability to other populations. Our differences are also our largest asset, in that we have access to patient populations that may be unavailable to other clinical investigators.

The following are the outcomes of a NAMCS-like visit survey conducted in our RRNeT practices to characterize accurately the patient population and the services we deliver to them. The primary purpose of this study was to describe outpatient visits to the practices of the Residency Research Network of Texas. Through careful documentation of visits across 9 clinical sites, we were able to describe the demographics of the RRNeT patient population, their reasons for visits, common diagnoses, medicines and other services ordered, and referral patterns.

## RESEARCH PLAN

Study Setting and Sample The Residency Research Network of Texas (RRNeT) is a collaboration of ten family medicine residency programs located in Austin, Corpus Christi, Dallas, Fort Worth, Garland, Harlingen, Lubbock, McAllen, and San Antonio (2 programs). About 100 family physician faculty and 300 family medicine residents see more than 300,000 patient visits per year. $55 \%$ of patients are Latino; $25 \%$ of them speak Spanish only. Approximately $42 \%$ of our patients have government sponsored health insurance, $17 \%$ have private insurance, whereas $27 \%$ are self-pay or utilize the county plan.

This was a study of family medicine visits in outpatient settings. These included visits with any patient (or patient's parent or guardian) who consents to documentation of the visit for research purposes. Study patients included infants, children, adolescents, adults, and seniors.

This was a cross-sectional survey of patients and primary care visits. The study used two data collection tools, namely a visit survey and a patient survey. The visit survey recorded patient demographics, including age, gender, race/ethnicity, and health insurance status. The survey also collected information pertaining to patient reasons for visits, common diagnoses, medicines and other services ordered and referral patterns. The patient survey was comprised of a set of questions about the patients' access to electronic communication such as cell phones and home computers.

## Procedure

In this study, research investigators randomly selected visits by physician. During the one month data collection period (May and June 2011), investigators identified all physicians (family physician or family medicine residents) working in each half-day clinic session. For each session they randomly selected one physician. Medical students shadowed the selected doctor during that session, observing and documenting all visits, for approximately 100 visits per site. Selected patients were also asked to complete the patient survey.

## RESULTS

| TX Region | No. of Patients |  |  |
| :---: | :---: | :---: | :---: |
